Farmer Willingness to Pay for Quality Bean Seeds—Nicaragua 2017 Survey

Overview

Identification	NicaraguaWTPbeansseed2017
Abstract	<p>A simple way to increase smallholder farmers' bean yields is to improve the quality of the seed used. Improved seed quality should lead to higher germination rates, better pest resistance and an overall healthier and more vigorous plants and thus higher yields. The use of higher quality seed in a smallholder context can be hampered by several factors including availability, trust in the source, and the price premium required to purchase. This dataset is based on a study that focused on the later and investigated farmers' willingness-to-pay (WTP) for higher quality seed. Double-blind farmer-run field trials in 12 villages in Nicaragua were conducted using three different qualities of bean (<i>Phaseolus vulgaris</i>) seed of the same variety - Certified, Quality Declared (QDS), and recycled. Village farmers participated in two field days (at flowering and just before harvest) to observe plot differences and participated in ranking activities. To elicit the WTP for the different seed qualities, 10-50 farmers in each village participated in both an auction (Becker-DeGroot-Marschak mechanism) and a real choice experiment (RCE) during the last field day. Both the auction and RCE were incentivized in that participants were told that one will be chosen randomly and the outcome enforced (i.e., the farmer would have to buy seed at the chosen price). RCEs are relatively new and, relative to auctions, are thought to better replicate an actual shopping decision. This set includes data from the BDM and RCE experiments, plot ratings by farmers during the two field days, and farmer survey conducted after the BDM and RCE experiments.</p>
Unit of Analysis	Farmer

Scope & Coverage

Countries	Nicaragua
Geographic Coverage	10 villages in four Departments -- Estelli, Jinotega, Madriz, and Matagalpa
Universe	Bean growing farmers in the selected municipios in Nicaragua

Producers & Sponsors

Primary Investigator(s)	Mywish Maredia, Michigan State University Sean Posey, Michigan State University Byron Reyes, CIAT Robert Shupp, Michigan State University

Methodology

Methodology: Double-blind field experiments (FE) were established in 10 villages in north-western Nicaragua (one FE per village).

Each seed type for variety *phaseolus vulgaris* were procured by the researchers and given to the host farmers to plant on 10x10m plots using their management practices. Plots were assigned labels (triangle, square and circle) and referred to by these shapes as plot IDs throughout the study. (Certified seeds were planted on plot 'circle', QDS on plot 'square', and Recycled seed on plot 'triangle'). Two field days were held in each village one at flowering stage (Field day 1) and one 2 weeks prior to harvest stage (Field day 2). During each field day, farmers completed plot performance evaluation and rating of plots based on observable characteristics. On average, 23 Farmers from each village participated in Field day 2 (ranged from 13-44).

Once farmers had learned how the different types of seeds performed in the field, willingness to pay experiments using Becker-DeGroot-Marschak (BDM) mechanism and real choice experiments (RCE) were carried out during Field Day 2. In BDM mechanism, participants do not bid against other people, but only against themselves. Endowment was given to farmers for the BDM/RCE (C\$40). Each farmer was given a bidding sheet and asked to "bid" their maximum willingness to pay for 1lb. of seed of each type (circle, square and triangle) knowing that one seed type would be chosen randomly and the bid for that seed would then be compared to a randomly drawn price. If a farmer's bid was greater than or equal to the randomly drawn price, then that farmer buys that seed for the randomly drawn price (NOT their bid).

For RCE, we implemented a 12 choice orthogonal experiment. Each choice varied in seed quality (circle, square and triangle) and price (Cordobas 14, 21, 28 and 34) and included an opt out. Farmers broke into 4 groups and each saw the choices in a different order. Farmers made choice knowing that if RCE was chosen for payment then one of the 12 choices would be randomly chosen and their choice would be implemented. During the farm household surveys, for a subset of farmers, a hypothetical choice experiment (HCE) was also conducted using the actual samples of the three seed products.

Data Collection

Data Collection Mode	Data was collected using the traditional paper-and-pen-interview (PAPI) method based on structured questionnaires.

Variables Description

Dataset contains 225 variable(s)

File : HH_level_public

Department: Department

Information [Type= discrete] [Format=character] [Missing=*]

Statistics [NW/ W] [Valid=242 /-] [Invalid=0 /-]

Value	Label	Cases	Percentage
Estel�		87	36.0%
Jinotega		21	8.7%
Madriz		64	26.4%
Matagalpa		70	28.9%

Warning: these figures indicate the number of cases found in the data file. They cannot be interpreted as summary statistics of the population of interest.

Municipio: Municipio

Information [Type= discrete] [Format=character] [Missing=*]

Statistics [NW/ W] [Valid=242 /-] [Invalid=0 /-]

Value	Label	Cases	Percentage
Condega		57	23.6%
La Concordia		21	8.7%
Matagalpa		50	20.7%
Pueblo Nuevo		30	12.4%
San Dionisio		20	8.3%
San Lucas		64	26.4%

Warning: these figures indicate the number of cases found in the data file. They cannot be interpreted as summary statistics of the population of interest.

x1: village id

Information [Type= discrete] [Format=character] [Missing=*]

Statistics [NW/ W] [Valid=242 /-] [Invalid=0 /-]

Value	Label	Cases	Percentage
A1		44	18.2%
A2		13	5.4%
A3		15	6.2%
A4		15	6.2%
A5		22	9.1%
A6		42	17.4%
B2		20	8.3%
B3		26	10.7%
B4		24	9.9%
B6		21	8.7%

Warning: these figures indicate the number of cases found in the data file. They cannot be interpreted as summary statistics of the population of interest.
